

VASCULAR PLANT DIVERSITY AND BIOLOGICAL SPECTRUM OF GALIYAT VALLEY, DISTRICT ABBOTTABAD, KHYBER PAKHTUNKHWA, PAKISTAN

Safeer Ullah¹, Asad Ullah¹

Centre of Plant Biodiversity, University of Peshawar, Khyber Pakhtunkhwa, Pakistan

Abstract- The present study was aimed to assess the vascular plant diversity in term of floristic composition, habit, life form and leaf size classification at Galiyat valley of district Abbottabad, KP. The vascular plant species investigated during the research were 343 distributed in 250 genera and 87 families. Pteridophytes were 7 species (2.04%), Gymnosperms 6 species (1.74%), Angiosperms (monocots) with 54 species (15.74%) and Angiosperms (dicots) with 276 species (80.46%). The habit of different plant species showed that herbs were 228 species (66.47%), Shrubs 63 species (18.36%), trees 41 species (11.95%) and climbers were 11 species (3.20%). The leading family with highest number of species and genera was Asteraceae with 32 species and 25 genera followed by Poaceae with 31 species and 19 genera. The other dominating families include, Lamiaceae (28 spp. & 17 genera), Rosaceae (22 spp. 11 genera), Ranunculaceae (16 spp. & 10 genera), Fabaceae (11 spp. & 8 genera), Apiaceae (10 spp. & 9 genera), Polygonaceae (10 spp. & 8 genera), Caprifoliaceae (10 spp. & 6 genera). Remaining families were represented by less than 10 plant species. Life form classes showed that Therophytes were dominating with 119 species (34.69%), followed by Hemicryptophytes with 61 species (17.78%). The other life form classes were Geophytes 38 species (11.07%), Megaphanerophytes 46 species (13.41%), Nanophanerophytes 42 species (12.24%), Chamaephytes 29 species (8.45%) and Lianas 8 species (2.33%). The study of leaf size classification showed that Microphylls were dominating with 134 species (39.06%) followed by Nanophylls with 98 species (28.57%). Leptophylls were 33 species (9.62%), Mesophylls 72 species (20.99%) and Megaphylls were 06 species (1.74%).

Index terms - Biological spectrum, floristic composition, Galiyat, habit, life forms, leaf size, vascular plant diversity.

INTRODUCTION

District Abbottabad is located in Hazara division of Khyber Pakhtunkhwa, Pakistan and extended over an area of over 1967 km². The geographical coordinates of the area are 34° 06' N latitudes and 73° 20' E longitude. Galiyat region, or hill tract, is a narrow strip or area roughly 50-80 km north-east of Islamabad, Pakistan, extending on both sides of the Khyber Pakhtunkhwa-Punjab border, between Abbottabad and Murree. The beautiful region of Galiyat is situated in district Abbottabad, Khyber Pakhtunkhwa, spreading over an area of 250,000 acres with a population of about 189,426 (GoP, 2017). It is a long valley of 40 km and is dominated by the moist temperate forest (Jamal and Khadija, 2009). Galiyat are the hub of local and foreign tourists and the geographic coordinates of the area are from 33°53'15" to 34°11'25" N latitudes and from 73°16'43" to 73°25'23" E longitudes. The elevation ranges from 1450 to 3033 m presenting a diversified flora and fauna. Winter is severe and snowfall takes place in hilly areas *i.e.*, above Changa Gali and Barian in Bara Gali, Nathia Gali, Ayubia, Mashkpuri and Miranjani top mainly in the months of December, January and February (Ahmad and Afzal, 2014). The geologic time scale indicate the geological origin of the area from Indian plate which is 40 to 170 million years old (Shaheen and Asad, 2002). Weather in summers is temperate with long monsoon season whereas in winter, it is severe cold. Snow season remains from mid-December to mid-February (Shinwari and Khan, 2000). Mean annual rainfall is 1500 mm (with heavy winter snow) and 11°C respectively (Ahmad and Afzal, 2014).

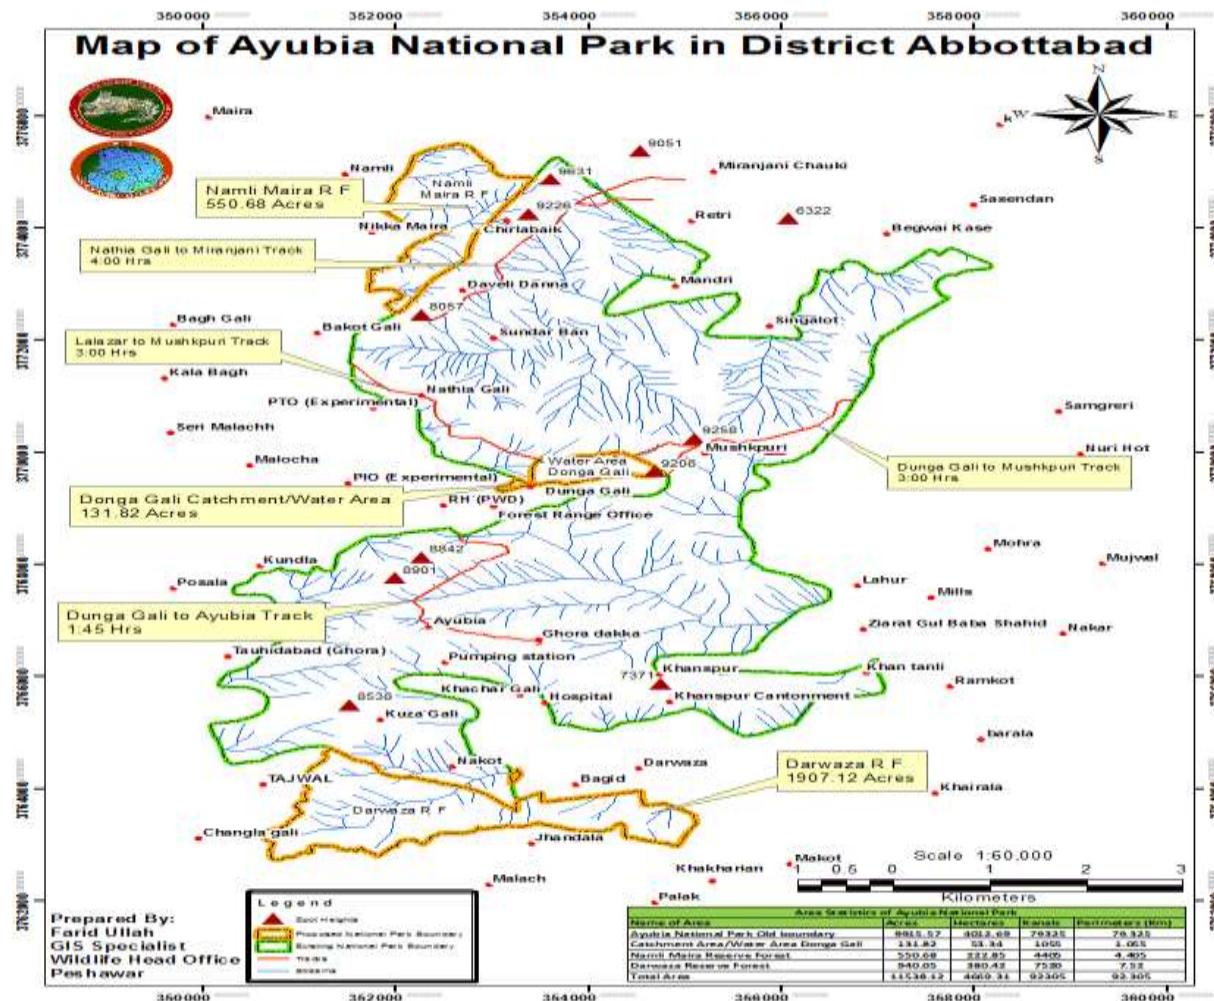

Fig.1 Map of Galiyat showing surrounding villages and tracks (Wildlife Department Khyber Pakhtunkhwa).

Floristic checklists provide the most useful botanical data of a specific geographical area. Floristic composition is a good marker, as changing kind of floristic composition in various intimate milieu reveal the presence of different ecological factors; lead to intraspecific and interspecific diversity (Safidkon et al., 2003). Floristic study of an area helps to analyze the plant wealth and its potential values. The identification of local plant species in an area is of immense importance to know the existence of specific species, their growing seasons, determining new species and effect of climatic factors like temperature, grazing and other stresses on vegetation of an area (Ali, 2008; Ahmad et al., 2008). Some other contributors to floristic composition of various localities are (Adnan et al., 2014; Ahmad et al., 2009; Ahmad et al., 2016; Bibi et al., 2014; Ibrar et al., 2015; Haider and Ibrahim, 2022; Manan et al., 2022; Bibi et al., 2019). The study area has a great potential to support a thick plant biodiversity due to microhabitats and diverse topographic features. The study was designed to document the floristic composition and biological spectrum of the research area. It will be helpful for the conservation and sustainable utilization of plant natural resources and for future investigations.

MATERIALS AND METHODS

A detailed field survey was carried out to record and document the floristic composition and biological spectrum of Galiyat valley, District Abbottabad, Khyber Pakhtunkhwa, Pakistan. Field trips were arranged at regular intervals of the year 2019-2022. Plant specimens were collected, identified, dried and pasted on herbarium sheets. Chemical insecticides and pesticides were used to avoid insect and pests attack on the preserved specimens. The specimens were identified with help of literature (Ali et al., 2016; Stewart, 1972; Nasir and Ali, 1970-1989; Ali and Nasir, 1989-1991; Polunin and Stainton, 1990; Ali and Qaiser, 1993-2022). Life form and leaf size of the collected plant species were identified with the help of Raunkiae (1934). The collected plant specimens were

deposited at Herbarium Centre of Plant Biodiversity, University of Peshawar and Herbarium, Department of Botany, University of Peshawar.

RESULTS

A total of 343 plant species, distributed in 86 families and 250 genera, were recorded and collected from the research area. Families with highest number of plant species were Asteraceae with 32 species (9.32%) and 25 genera (10%) followed by Poaceae with 31 species (9.03%) and 19 genera (7.6%). The other families include, Lamiaceae (28, 8.16% spp. 17, 6.8% genera), Rosaceae (22, 6.41% spp. 11, 4.4% genera), Ranunculaceae (16, 4.6% spp. 10, 4% genera), Fabaceae (11, 3.2% spp. 08, 3.2% genera), Apiaceae (10, 2.9% spp. 09, 3.6% genera), Polygonaceae (10, 2.9% spp. 08, 3.2% genera), Caprifoliaceae (10, 2.9% spp. 06, 2.4% genera). Remaining families were represented by less than 10 plant species (Table 1, Fig. 2).

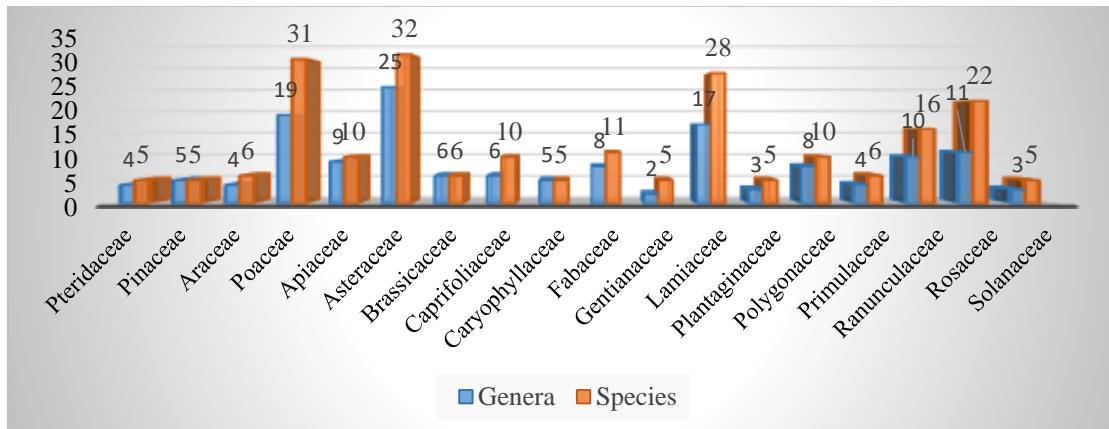

Fig.2. leading plant families with their number of species and genera

Pteridophytes were 7 species (2.04%), Gymnosperms 6 species (1.74%), Angiosperms (monocots) with 54 species (15.74%) and Angiosperms (dicots) with 276 species (80.46%) (Fig. 3).

Dicot 276/80.46%

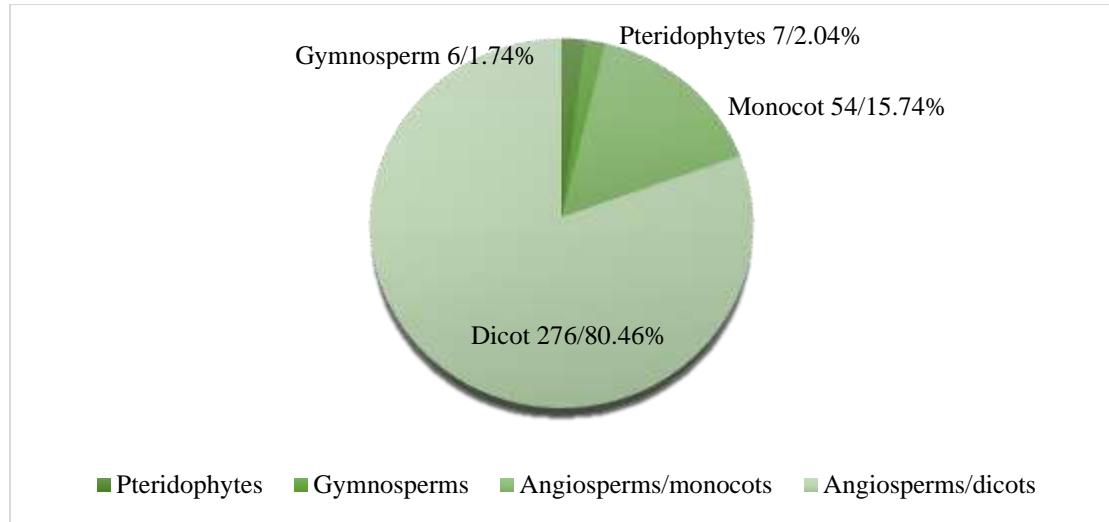

Fig.3. Major Divisions of plants growing in the area.

The habit of different plant species showed that herbs were 228 species (66.47%), Shrubs 63 species (18.36%), trees 41 species (11.95%) and climbers were 11 species (3.20%) (Fig. 4).

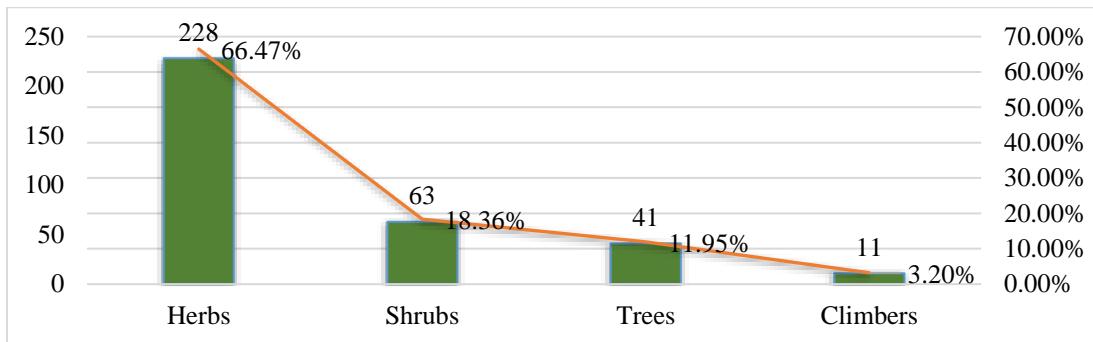

Fig.4. Habit of plant species growing in the research area.

Life form classes showed that Therophytes were dominating with 119 species (34.69%), followed by Hemicryptophytes with 61 species (17.78%). The other life form classes were Geophytes (38 spp. 11.07%), Megaphanerophytes (46 spp. 13.41%), Nanophanerophytes (42 spp. 12.24%), Chamaephytes (29 spp. 8.45%) and Lianas (8 spp. 2.33%) (Fig. 5).

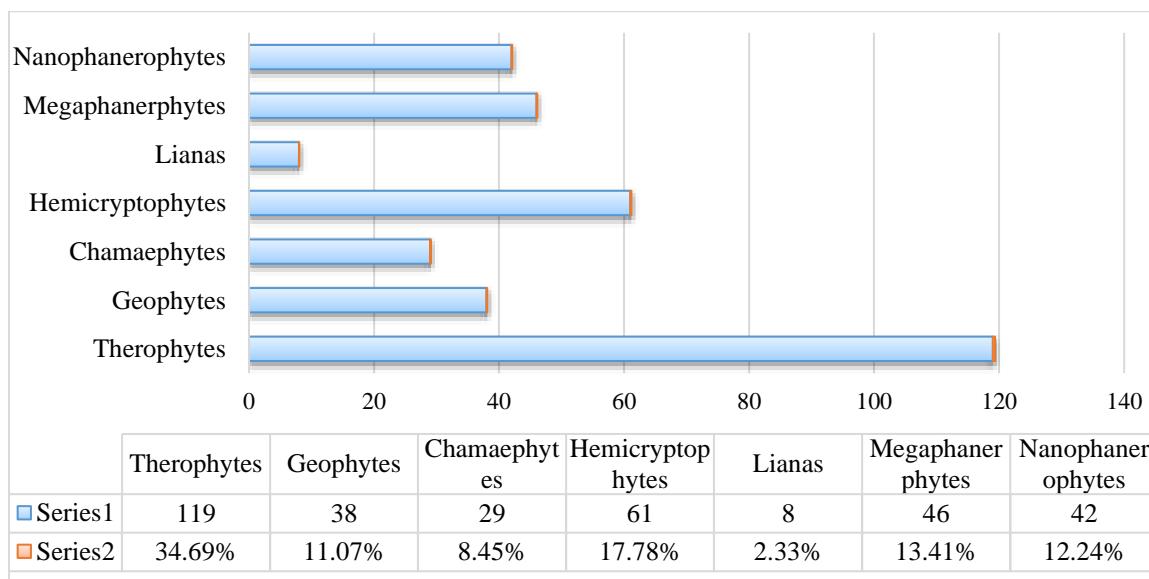

Fig.5. Raunkiaer life form classes of plant species in the area.

Leaf size classification showed that Microphylls were dominating with 134 species (39.06%) followed by Nanophylls with 98 species (28.57%). Leptophylls were 33 species (9.62%), Mesophylls 72 species (20.99%) and Megaphylls were 06 species (1.74%) (Fig. 6).

DISCUSSION

The floristic structure of an area is reflected by its vegetation. The sum of all species either wild or cultivated is the flora of a particular region (Longhi et al., 1992). The ecological amplitude of plant species and their interaction with the environment and other species is also revealed by the floristic list of an area (Giusti et al., 1995). The present study showed that according to plant habit the number of herbaceous plants were most dominant with 228 species. These findings are congruent with the other researches in different ecological regions (Khattak et al., 2015; K. U. Khan et al., 2015; Ahmad et al., 2016; Rehman et al., 2016; Khan et al., 2016; Ilyas et al., 2018; Anwar et al., 2019; Manan et al., 2022 and Haider and Ibrahim, 2022). Various plant species adapt with different environmental conditions which shows their life form. To describe vegetation adaptation is of immense importance for plant species survival (Mera et al., 1999; Cain and Castro, 1959). In the research area life forms of all species were arranged into different life form classes which showed that therophytes were dominant with 119 species followed by hemicryptophytes with 61 species. Similar findings were observed by different researchers in other areas (Haider and Ibrahim, 2022; Bibi et al., 2019; Ali et al., 2018 and Khan et al., 2017). The ecological factors and their relation with the leaf size is very important because it play key role in studying the vegetation structure at regional scale (Floret et al., 1990). The leaf size spectrum showed that Microphylls were dominating with 134 species (39.06%) followed by Nanophylls with 98 species (28.57%). Leptophylls were 33 species (9.62%), Mesophylls 72 species (20.99%) and Megaphylls were 06 species (1.74%).

CONCLUSION

The present research records the rich floral biodiversity of Galiyat that will serve as reference work for the further studies. The present work is a part of the whole area and yet a detailed study is required to explore the area floristically and ecologically.
